

Fleet Numerical Meteorology & Oceanography Center Verification Status Overview

Raymond C. Lee
Regional Modeling Division – COAMPS
Modeling Department Verification Lead

The overall classification of this brief is: **UNCLASSIFIED**

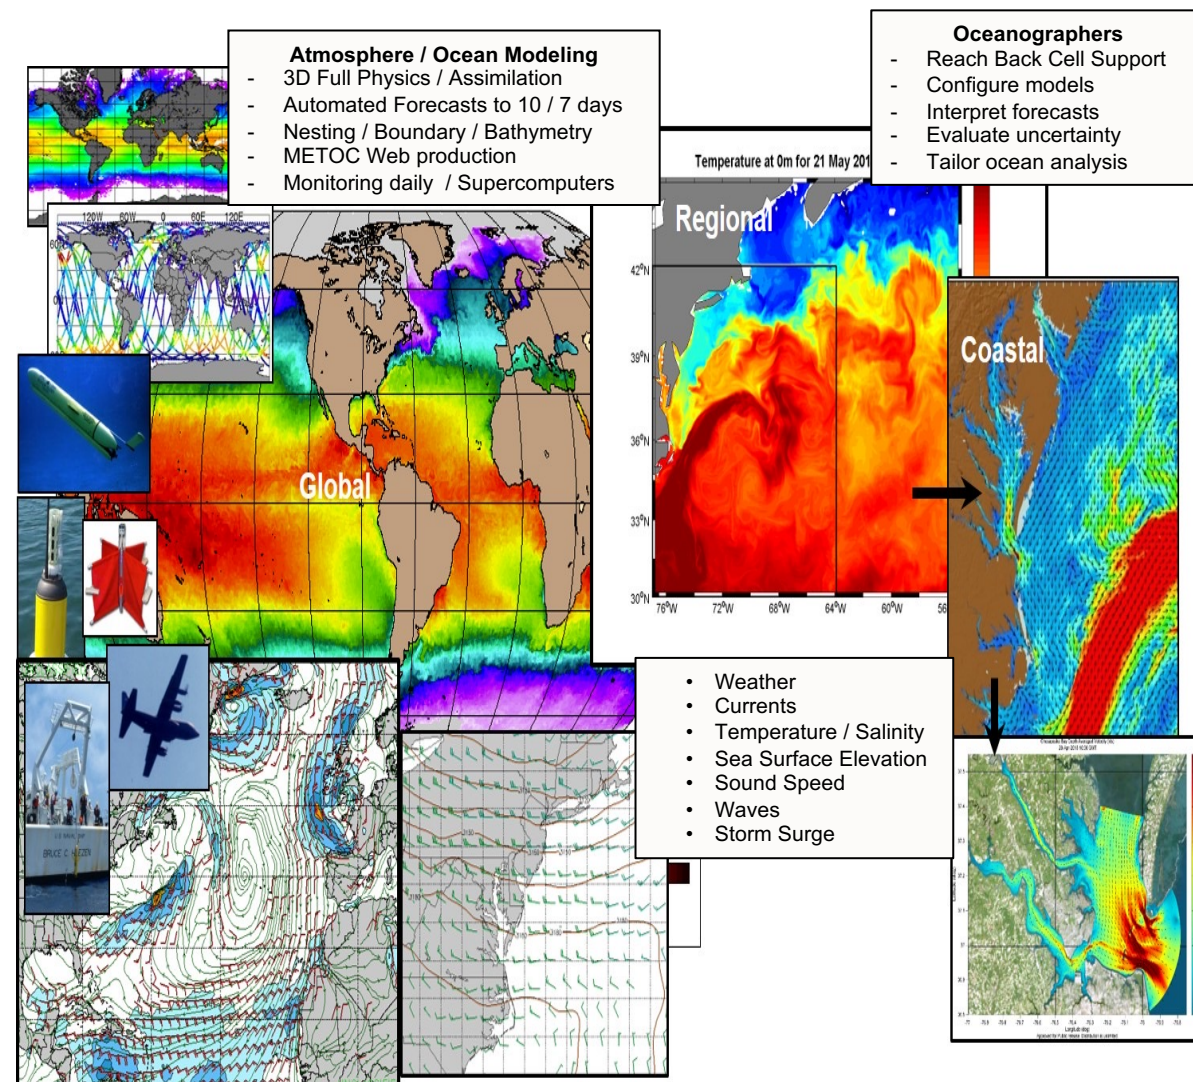

APPROVED FOR PUBLIC RELEASE. DISTRIBUTION IS UNLIMITED.

The views expressed in this presentation are those of the presenter and do not necessarily reflect the official policy or position of the Department of the Navy, Department of Defense nor the United States Government

- US Navy's premier environmental modeling center
- Responsible for numerical weather and oceanographic predictions to the fleet
- ~20 military officers
- ~120 civilians and contractors
- Approximately 35 modelers in the Modeling Department
- 5 of the 35 have limited time (<15%) to work on verification code improvements

Assimilate Obs -> Run Models -> Release Model Data

FNMOOC's Current Model Inventory

Global:

ESPC EFS
NAVGEM
NAVGEM EFS
GOF5 (ocean)
NAAPS (aerosol)
Wave Watch 3
WW3 Ensemble
Derived Products

Regional:

'Static' COAMPS-ATM (x120)
'Moving' COAMPS-ATM
COAMPS-NCOM (ocean, x30)
WW3 Regional (x100 areas)
WW3 TC-OFCL
SWAN (coastal, x200 areas)
DELFT3D (x100 areas)

Specialized:

COAMPS TC (x7 storm)
REA COAMPS
AAP (acoustic)
CSIPS (surge)
FST (synthetic)
Drift / SAR prediction
Standard Ocean Area
Assessments (x15)
Water Sampling Plan

FNMOOC has ~35 modelers and ~10 forecasters in the Modeling Department to support all of these models and products when fully staffed...
We need verification that is flexible and low maintenance

Model Verification

• Deterministic Model Verification

- How have the models been performing? Which is best? On which model should a sailor base their forecast? Does this model accurately predict what will happen at the ship’s location?
- How can the Naval Research Laboratory (NRL) best leverage these results to improve future versions of the models?
- Near Real-time Ocean Verification is developed
 - FNMOOC is evaluating the optimal distribution mechanism for releasing these results
- Near Real-time Atmosphere and Wave Verification available
- Verification results released at multiple classification levels

• Ensemble Model Verification

- Verification of the probabilities of occurrence for Ensemble model forecasts

• Tropical Cyclone (TC) Model Forecast Verification

- Primarily for Joint Typhoon Warning Center (JTWC) forecasters to see how various TC forecast aids have been performing in near-real-time
- Forecasters can know which model has been handling a storm well while the storm is still active

SOUTHERN CALIFORNIA Forecast Verification Page

AREA: SOUTHERN CALIFORNIA COAMPS Resolution: 15km
 Current DTG: 20230726 23:00Z Last Forecast Verified: 2023072100 Verification Date: 2023072500

Standard | Precipitation | DMC | MVA | Surface Bias | Scatterometer | Visibility | Wave

Standard Products PARAMETER	SFC/UPR	Last 30 Days of Forecasts Ending On:						Previous Months

Upper Air Geopotential Height [m]	upper	●	00z	12z	All	00z	12z	All	00z	12z	All	●

Forward Verification Mode

Valid Area:

Trends & Tendencies

- Model Trends and Tendencies can help forecasters know typical model departures from observed values in specific situations
 - With FNMOC’s Climatology Division
 - In development
 - Continual staffing issues mean this long-term work continually gets pushed to the side

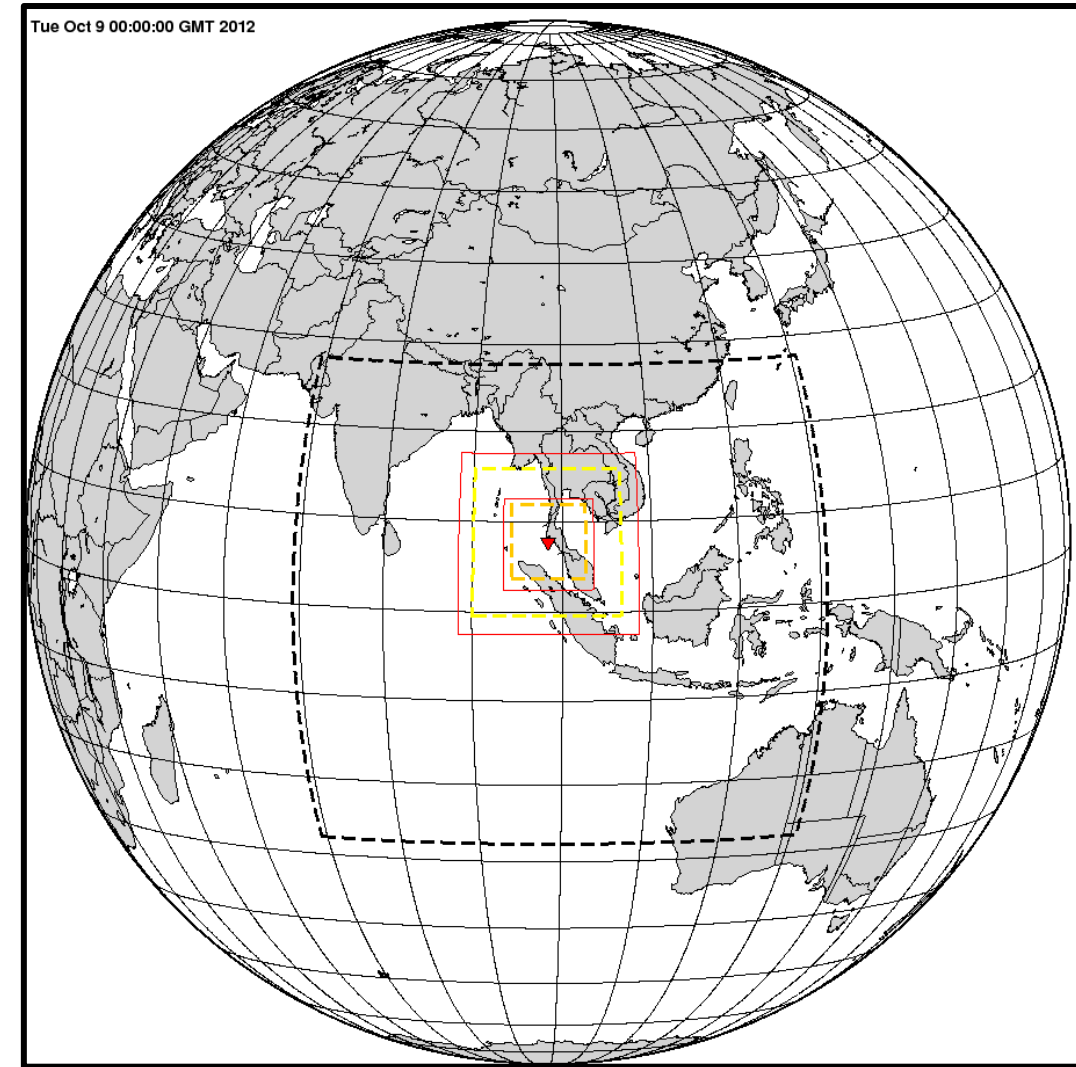

- We want feedback and forecaster knowledge as we develop this resource but getting these responses is difficult

Unique Challenge: 'Moving' COAMPS

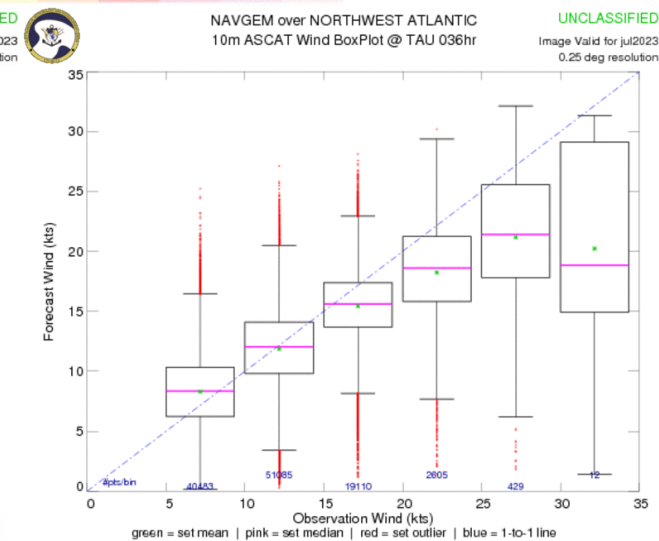

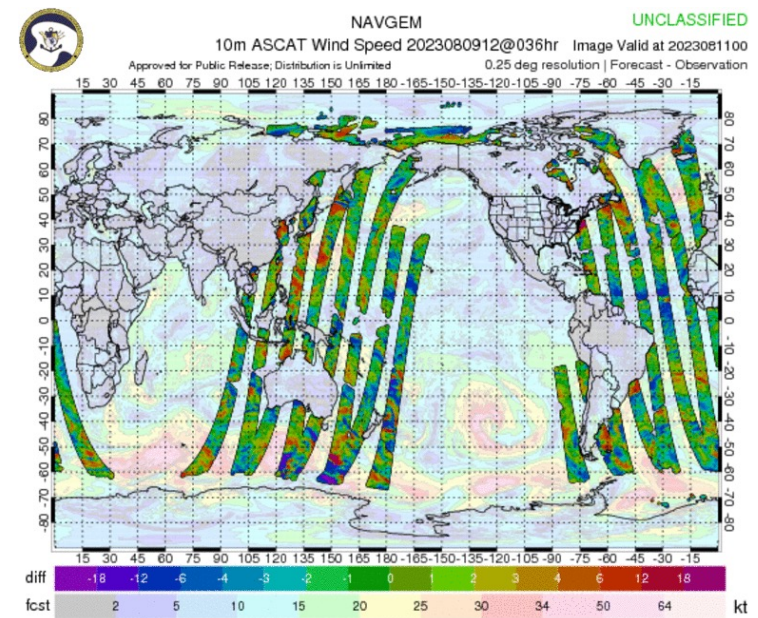

- Automated moving boxes for atmospheric and oceanographic wave support for ships at sea
- The problem is how do we produce near-real-time verification results that are meaningful for the ship when it moves to & through different climatic situations
- Classification levels can mean multiple input datasets of the same data type needing to be leveraged by the verification processes

Unique Challenge: Open Ocean Wind Verification

- Naval operations occur away from land-based stations
- How can we verify the 10m winds without surface stations?
- Scatterometer retrievals taken as 'truth' and compared to the models
 - Started in early 2015
- Inherent error due to biased observations
 - Look for patterns, not numbers

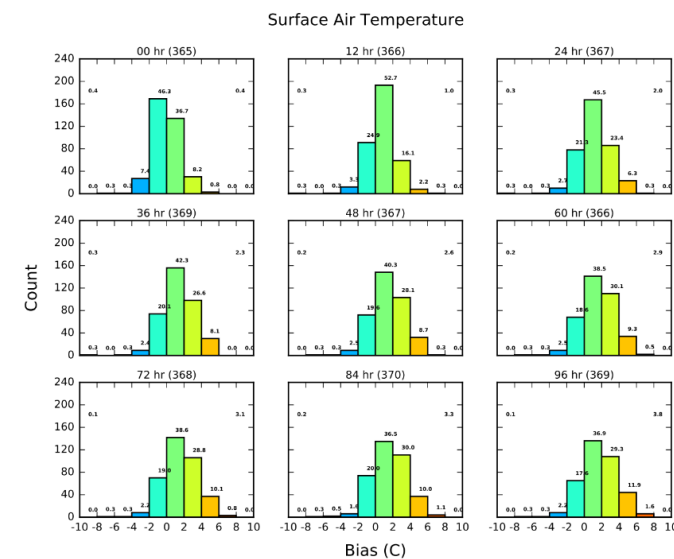

Machine Learning for Automatic Stoplight Results

- Machine Learning approach to automatically determine model reliability and skill
 - Investigating but limited work effort assigned
- Clustering based on RMSE, Bias, and geographic location for pattern identification
- Geo-located clustering gives insight on differences in latitude/longitude, elevation, season, and distance from the coast
- Provides an objective view of results contrasting the more subjective interpretation currently done for the wide variety of results
- Goal is to assign a single stoplight color to describe a region's performance
 - Easy for sailors to understand
 - Easy for leadership to understand

- Automatic Verification Improves
 - Efficiency: Less time and effort needed
 - Frequency: Weekly or Daily verification instead of focusing on Monthly results
- Identify patterns & insights for improvements
- Gaussian Naïve Bayes, Decision Tree, Random Forest methods applied

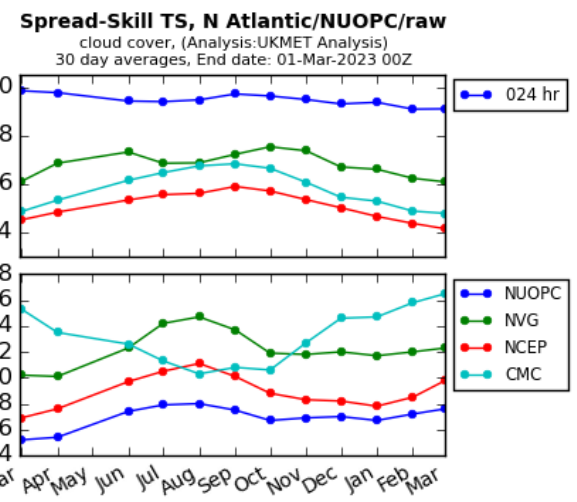

Code Challenge: Cloud & Visibility Verification

- FNMOC had visibility verification for dust/aerosols, and hydrometeors (2015-2018)
 - It leveraged parts of 5 different code bases making it unmanageable and unmaintainable
 - No direct cloud verification. The hydrometeor visibility was mostly haze/rain detection
- NRL delivered cloud verification but FNMOC wasn't able to run it due to non-IA approved code

- Marine fog is a major problem for mariners (Human error, weather and wave-related accidents top the list for causes of mishaps at sea)
- How to verify marine fog if few to no observations exist in the ocean?

- Ensemble model cloud verification exists but leverages UKMET's analysis of clouds as truth
- Each of these codes exist as completely separate programs coded in different languages for one specific model. This greatly increases the difficulty of making one application serve as a verification tool for the full suite of models at FNMOC

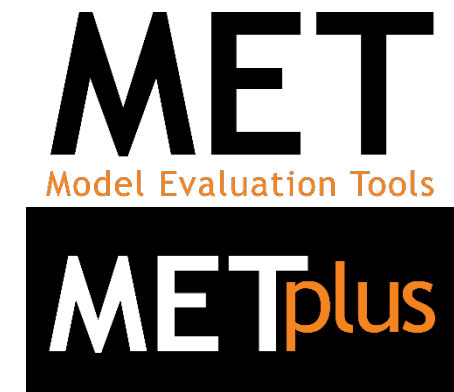

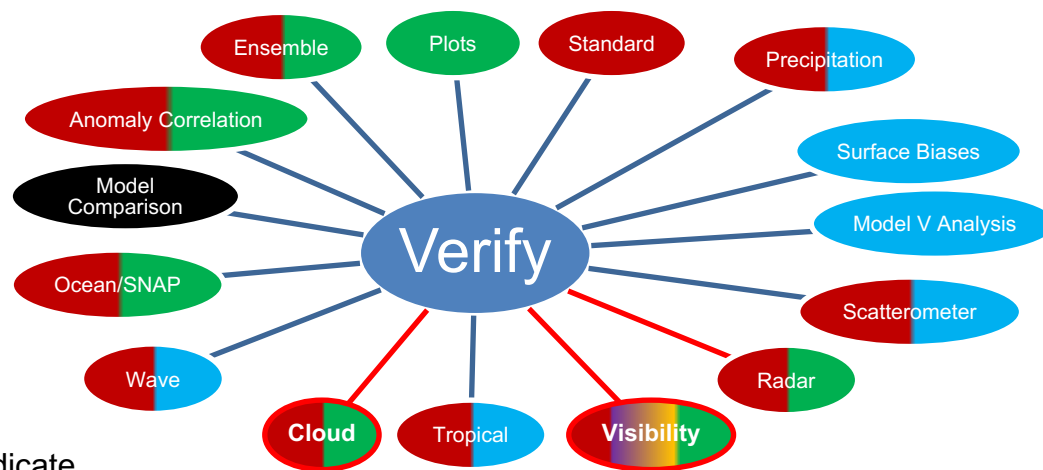

Where FNMOOC is Heading

- FNMOOC will be accepting delivery of a version of MetPlus modified by NRL-MRY for IA requirements to begin to unify the multiple different verification codes currently used.

- This will bring FNMOOC in alignment with other centers and current verification trends.
- We hope this also allows us to expand the verification support we can provide

FORTTRAN
IDL
PYTHON
C+
Grads
Other

Red spoke lines indicate non-operational status

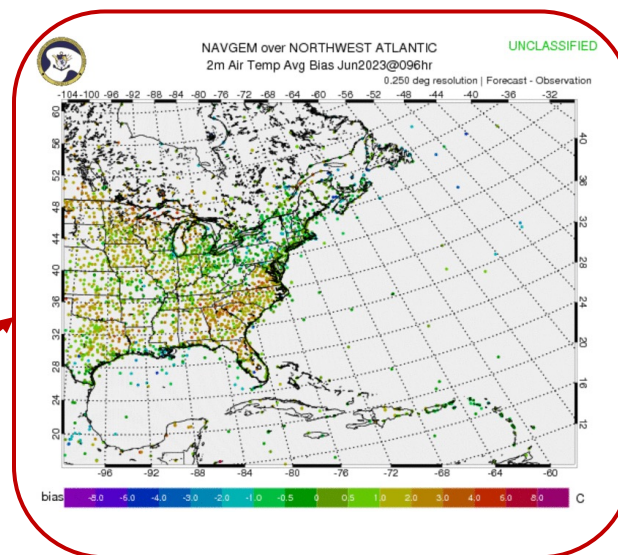

What Does FNMOC Need?

- Simple to understand output images
 - The sailors making the forecasts are mostly high-school grads with 4-5 years of METOC experience
 - They won't use verification if it doesn't make sense to them!
- Low bandwidth images
 - Limited numbers of small file size images that convey all the sailor needs to know

- Simple unified code which is easy to maintain
- Easy to run for many areas
 - Including different nest/resolutions of the same model area.
 - Including model areas which can move
- Ocean, Wave, and Atmospheric models ideally need to be supported

- Highly technical images or results to assist NRL's continuing improvement of the models
 - Yes, this contradicts the 'simple' image the sailors need from above
- Images showing both station and area average results to locate small regional biases
 - The small red dot (circled right) represents all the data in the entire other image (far right)

Thank you
